PVG 16 Proportional Valve Group

General information

PVG 16 introduction

The PVG 16 is a hydraulic load sensing proportional valve group designed to give maximum flexibility in design and build concept. The PVG 16 is designed as a load sensing directional control valve which will lead to increased application efficiency, reducing cooling requirements and fuel saving compared to conventional directional control valves. When the pump is started and the main spools in the individual basic modules (6) (see PVG 16 sectional view on page 7) are in the neutral position, oil flows from the pump, through connection P, across the pressure adjustment spool (4) to tank. The spring in the pressure adjustment spool determines the pump pressure (stand-by pressure) in neutral.

When one or more of the main spools are actuated, the highest load pressure is fed through the shuttle valve circuit to the spring chamber behind the pressure adjustment spool (4), and completely or partially closes the connection to tank. Pump pressure is applied to the right-hand side of the pressure adjustment spool (4). The pressure relief valve (1) will open should the load pressure exceed the set value, diverting pump flow back to tank.

With a non pressure-compensated basic module incorporating a load drop check valve (8) in channel P, the check valve prevents return oil flow.

The basic module can be supplied without the load drop check valve in channel P for functions with overcentre valves.

The shock and suction valves PVLP (7) with fixed setting on ports A and B are used for the protection of the individual working function against overload and/or cavitation.

In the closed center version an orifice (3) and a plug (5) have been fitted instead of the plug (2). This means that the pressure adjustment spool (4) will only open to tank when the pressure in channel P exceeds the set value of the pressure relief valve (1).

Alternatively a dedicated PVPV inlet for variable displacement pumps can be used. In load sensing systems the load pressure is led to the pump regulator via the LS connection. In the neutral position the pump control sets the displacement so that leakage in the system is compensated for, to maintain the set stand-by pressure.

When a main spool is actuated the pump regulator will adjust the displacement so that the set differential pressure between P and LS is maintained. The pressure relief valve (1) in PVP should be set at a pressure of approx. 30 bar [435 psi] above maximum system pressure (set on the pump or external pressure relief valve).

The PVG 16 is part of a whole family of PVG valves spanning a wide range of flow options. A common feature is the modular build concept combining stacks of flexible slice-sections across the families thus making it possible to build up a valve group to meet requirements exactly. The width and height of the valve remain unchanged whatever combination is specified.

The PVB 16 is available as a compensated basic module giving the features of load-independent flow control:

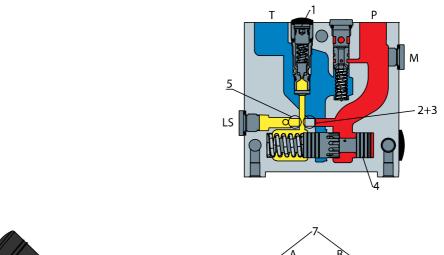

- Oil flow to an individual work function is independent of the load pressure of this function
- Oil flow to one function is independent of the load pressure of other functions.

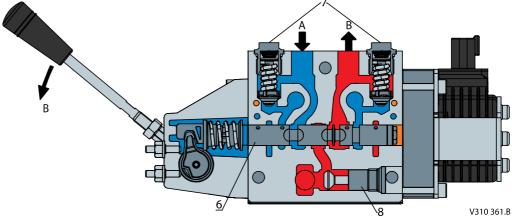

The PVB 16 employs the same compensation principle as the proven technology of the PVB 32 - the compensator maintains a constant pressure drop across the main spool (PVBS).

General information

The PVG 16 is the part of a whole family of PVG valves, spanning a wide range of flow options. A common feature is the modular build concept combining stacks of flexible slice-sections across the families, thus making it possible to build up a valve group to meet requirements exactly. The width and height of the valve remain unchanged, whatever combination is specified.

PVG 16 general features

- Load sensing directional control:
 - Proportional control of oil flow to a work function
- Modular build concept:
 - Up to 12 basic modules per PVG 16 valve group
 - Different, interchangeable spool variants
 - System pressure up to 350 bar [5075 psi]

PVG 16 Proportional Valve Group

General information

- Several types of port connection threads
- Possible combination with the rest of the PVG family either PVG 32, PVG 100 or PVG 120

PVP and PVS from PVG 32 portfolio

The PVG 16 interfaces directly with the PVG 32 product line. The PVG 16 valve is designed to be used with the existing PVP and PVS in the product portfolio from the PVG 32 family. When specifying a PVG 16 valve stack please refer to PVG 32 Technical Information, 520L0344 for detailed information on PVP and/or PVS.

Standard build (stack) of PVG 16 valve

Inlet section (PVP reused from the PVG 32 portfolio), 1–12 work sections (PVB) with individual flow controlling spools and end section (PVS reused from the PVG 32 portfolio). Each work section is actuated by manual lever, (PVM), electrical control signal (PVE) or hydraulic control signal (PVH).

Combining PVG family into a single valve stack

The PVG 16 can be used in conjunction with the other valves in the PVG family by combining them into a single valve stack. Hence a valve stack of PVG 32/16, PVG 100/16 or PVG 120/16 can be assembled. In a PVG 32/16 build no interface module is required as a PVG 16 slice can replace a PVG 32 slice. In a PVG 100/16 or PVG 120/16 build the standard interface modules known today (PVTI and PVGI respectively) are used.

PVG 16 Proportional Valve Group

Safety in systems

General safety considerations

All types and brands of control valves, including proportional valves, can fail. Therefore, the necessary protection against the serious consequences of a functional failure should always be built into the system. For each application an assessment should be made for the consequences of the system in case of pressure failure and uncontrolled or blocked movements.

Warning

It is the sole responsibility of the machine manufacturer to ensure that all performance, safety, and warning requirements of the application are met in his selection of products. The process of choosing the control system and subsequent safety levels is governed by the machine directive EN 13849.

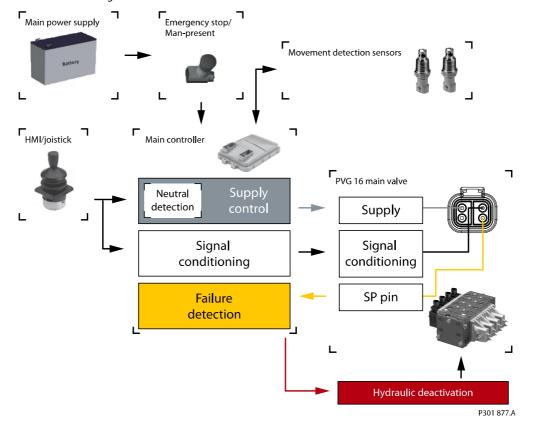

Control system example

An example of a control system using an aerial lift is shown below. Even though many Danfoss components are shown the example is concentrating on the PVG 16 control system.

This example breaks down the control system into smaller bits explaining the architecture in depth.

The function of the control system is to use the output from the PVEA Series 6 together with other external sensors to ensure the PLUS+1° main controllers correct function of the aerial lift.

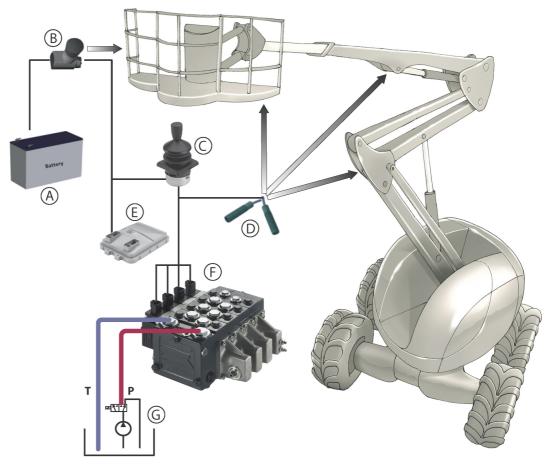

Electrical block diagram for the illustration below

Safety in systems

Example of a control system for manlift using PVE Fault monitoring input signals and signals from external sensors to ensure the PLUS+1° main controllers correct function of the manlift.

- **A:** Main power supply
- **B:** Emergency stop/man-present switch
- C: HMI/Joystick control
- **D:** Movement detection sensors
- E: Main controller
- F: PVG 16 valve group
- **G:** Hydraulic supply with deactivation

The equipment manufacturer is responsible for declaring that the control system used in the machine conforms with the relevant machinery directives.

PVB - compensated basic modules (work sections)

PVB work ports, interchangeable spools

The PVB (work section) is dedicated to distribute the oil flow coming from the inlet section through the Pgallery across the flow regulating main spool (PVBS) to work port A or B. Furthermore, the PVB returns the flow coming from the implement (motor or cylinder) through the work port A or B across the main spool to the T-gallery.

The PVB is available with two different work port threads:

- 3/8" BSP
- 3/4"-16 UNF (SAE-8)

Due to the modular concept of the PVG valves, the PVG 16 main spool (PVBS) can be interchanged by any other version of the PVG 16 main spool.

Versions available:

- 1. Compensated modules
- 2. Uncompensated modules
- 3. P-channel check valves
- 4. Shock valves (PVLP)

Work ports (A and B) image

PVBS spools image

Versions available:

Compensated PVB 16

- Basic module
- Basic module with facilities for shock and anti-cavitation valves (PVLP/PVLA)
- Basic module with one common LS for port A and port B

Non-compensated PVB 16

- Basic module
- Basic module with P-channel check valve
- Basic module with facilities for shock and anti-cavitation valves (PVLP/PVLA)
- Basic module with both P-channel check valve and facilities for shock and anti-cavitation valves (PVLP/PVLA)

Warning

Activation of many functions simultaneously can cause a reduced operating speed in sections with high load. Activation of a section with high pressure requirement in the same time as a section with low load can increase operating speed in the second section.

P-channel check valve

To prevent return oil flow, thereby lowering the load a P-channel check valve can be incorporated. For applications with over-center valves versions without the P-cannel check valve are also available.

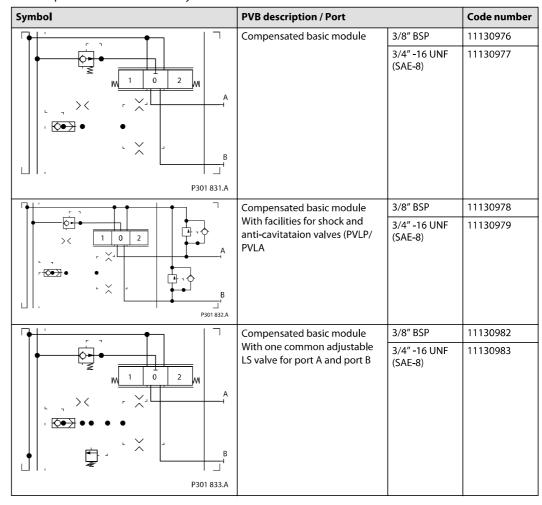

Shock valves

The shock valve (PVLP) with fixed pressure setting is used for protection of the individual work function against overload by removing any transient pressure spikes generated by the load.

	Basic work module	3/8" BSP	11101424
M		3/4" -16 UNF (SAE-8)	11101425

PVB oil flow characteristics

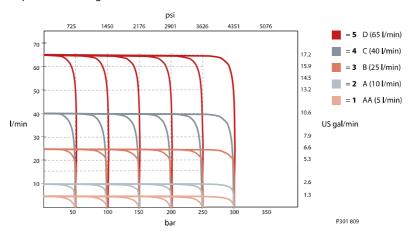

The oil flow from the work ports depends on the type of pump and in turn pump module. The difference is fixed displacement (Open Center) or variable displacement (Closed Center).

The letters AA, A, B, C and D denotes the spool flow sizes ranging from 5 l/min to 65 l/min [from 1.32 to 17.17 US gal/min]. All tests are done by using Tellus 32 @ 21mm²/s.

Load-independent oil flow characteristic, pressure-compensated PVB

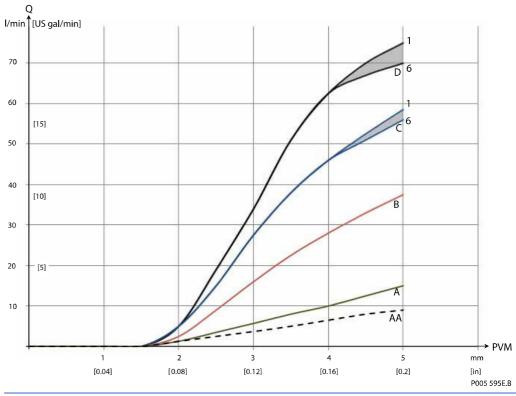

LS pressure limiting

PVB – compensated basic modules (work sections)

Oil flow as a function of spool travel with Open Center PVP

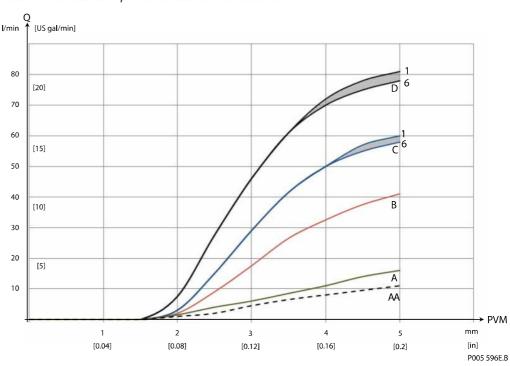

The flow is dependent on the supplied flow, Qp.

The characteristics apply to supply oil of 130 l/min [34.3 US gal/min].

The numbers 1 and 6 refer to the position of the PVB in the valve stack.

Oil flow as a function of spool travel with Closed Center PVP

PVG 16 Proportional Valve Group

PVB - compensated basic modules (work sections)

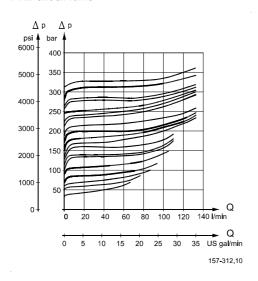

The flow is dependent on the pressure difference between the pump pressure and the LS signal. Normally the pressure difference is set at the LS pump regulator.

Set pressure difference between pump pressure and LS signal = 20 bar [290 psi].

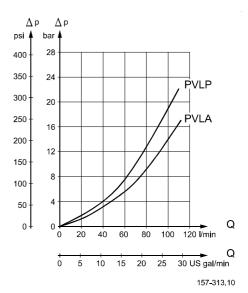

PVLP is set at an oil flow of 10 l/min [2.6 US gal/min]. The shock valve PVLP is designed to absorb shock effects. Consequently, it should not be used as a pressure relief valve.

PVBS, main spool

Flow control, spool characteristic

The spool is directly controlling the oil flow to and from the work ports. This flow is directly proportional with the spool travel. The spool travel is made up of 1.5 mm [0.06 in] dead band and 3.5 mm [0.14 in] active region in each direction giving 0-full flow. An additional 2.5 mm [0.1 in] travel in one direction in order to accommodate float functionality can be used dependant on choice of PVM.

Flow control

The spools are designed in such a way that the oil flow coming from the pump to the work ports are controlled by the spool travel. When the spool is moved it forms a variable orifice between the P-gallery and one work port and between the other work port and the T-gallery. The size of the orifice is directly linked to the traveled distance of the spool.

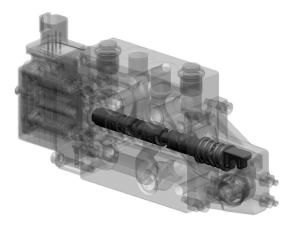

Spoos characteristic

The spools characteristic is linear with a soft start. The spool will have a progressive behavior from neutral to 10% of the full flow. From there it will be linear all the way to maximum flow.

Versions available:

- 1. Different flow versions
- 2. Open/closed in neutral
- 3. Float
- 4. Asymmetric spools

Sectional view - spool shown

Versions available:

Different flow versions

All the spools are flow controlled 4/4 spools. The spool comes in 5 different flow versions, all with a symmetrical flow: 5 l/min [1.32 US gal/min], 10 l/min [2.64 US gal/min], 25 l/min [6.60 US gal/min], 40 I/min [10.57 US gal/min], 65 I/min [17.17 US gal/min].

The flow specified is at 10 bar [145 psi] with 21 mm²/ sec [97 SUS].

Open/closed in neutral

The main spools for the PVG 16 are available with two different functions in neutral – open or closed. Open in neutral means that there is a throttled open connection across the main spool from both work ports A and B to the T-gallery. Open in neutral is generally used together with hydraulic motors. Closed in neutral means that there is no connection from work port A or B to the T-gallery across the main spool. Closed in neutral spools are generally used together with cylinders.

Warning

Using closed in neutral spools together with a hydraulic motor can cause a sudden and abrupt stop of the

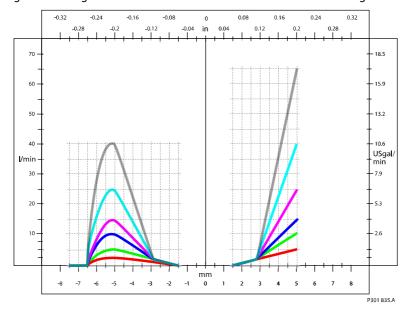

PVBS, main spool

Float

A spool with float function as well as normal actuation is capable of opening a connection between both work ports A and B to the T-gallery. This makes it possible for the oil in the e.g. cylinder to flow freely to the tank and the oil in the tank to flow freely from the tank to the work ports. This connection is opened when actuating 7.5 mm to the B direction (normal proportional control ends at 5 mm). Float is used if an application is to move freely back and forth to e.g. follow rough terrain.

Asymmetric spools

Asymmetrical main spools (PVBS) are designed for use with cylinders whose rod and piston sides differ greatly in volume. When operating with a symmetrical main spool, the difference in volume causes the cylinder's speed to be different in lifting versus lowering situations, given the same set point. If you want the same speed both in lifting and in lowering situations, you need an asymmetrical main spool. Asymmetrical spools have a linear flow characteristic with a progressive soft start. The soft start quarantees a good resolution in the low flow area where fine metering is needed.

PVBS, main spool

How to select the correct spool

Calculate your cylinder's piston-rod ratio using $\frac{D_1^{\ 2}}{D_1^{\ 2}-D_2^{\ 2}}$

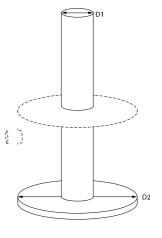

2. Use the result to find the right asymmetrical main spool in the table

Example

- flow request = 25 l/min
- use with PVE
- piston diameter = $150 \text{ mm} = D_1$
- rod diameter = $100 \text{ mm} = D_2$
- 1. Calculate your cylinder's piston-rod ratio

Equation:
$$\frac{D_1^2}{D_1^2 - D_2^2} = \frac{(150 \text{ mm})^2}{(150 \text{ mm})^2 - (100 \text{ mm})^2} = 1.8$$

2. Use the result to find the right asymmetrical main spool A piston-rod ratio of 1.8 for spools with a 25 l/min flow cannot be found in the table with code numbers. Therefore, we round to the nearest ratio (1.6). The spool with a 25 l/min flow and a cylinder ratio of 1.6 has the code number 11109645.

Actuation

The main spool in the PVG 16 can be actuated by one of three means. One is a lever for manual actuation, the second is electrically by a PVE and the third is hydraulically by a PVH. By actuating the main spool with a PVM or PVE the return spring of the spool will act with a force equivalent to 77 N [12.5 bar]. By actuating the main spool with a PVH the return spring will act with a force equivalent to 268 N [23 bar].

PVM and PVH - mechanical actuation modules

PVM and PVH general information

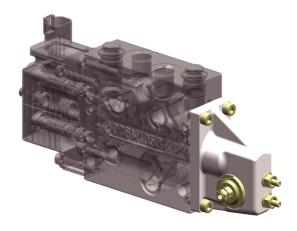

The PVM and PVH are two ways of mechanically controlling the flow from the work ports. The flow is controlled either by an operator using a lever or from a distance by a hydraulic joystick.

These are types of mechanical actuation modules for the PVG 16:

- PVM a fully manual lever controlled module
- PVH a hydraulic controlled module
- PVMD cover

Versions available:

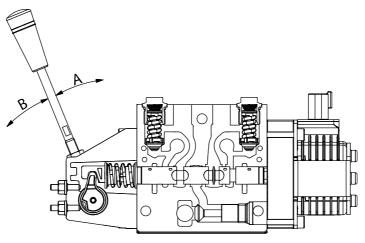

- 1. PVM with float control
- 2. PVM without adjustment screws
- 3. PVM with adjustment screws

PVM actuation module

The PVM consists of an aluminum base mounted on the end of the valve slice and a lever. When actuating the lever the operator is directly pulling or pushing on the main spool inside the valve hence controlling the flow. The lever has a travel of 16° in either direction from neutral. Actuating the lever fully will move the spool all 5 mm and give full flow. The lever can be mounted / removed without having to remove the PVM base. The PVM can be combined with any PVE, PVH or PVMD (cover).

PVM actuation module

Versions available:

PVM with float control

PVM and PVH - mechanical actuation modules

If an application with float functionality is needed this PVM is used. It is used when float position is with manual operator actuation. There are no adjustment screws available for this PVM version. The setting of this PVM is 5 mm spool travel in the A direction and 7.5 mm spool travel in the B direction giving float.

PVM without adjustment screws

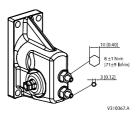

The standard PVM without adjustment screws will allow a spool travel of 5 mm in either direction. Full lever movement to one side will give full flow to the work ports. When the spool is moved 5mm it will stop due to a mechanical limitation build into the PVM base.

· PVM with adjustment screws

The standard PVM without adjustment screws will allow a spool travel of 5 mm in either direction. The spool travel in either direction can be limited by the adjustment screws. This will limit the flow out of the work ports thereby reducing the speed of an application.

The spool travel is adjusted by first loosening the nut then adjusting the pinol screw. After adjustment the nut must be tightened again.

Technical characteristics for PVM

PVH actuation module

The PVH is an aluminum plate with two threaded connections. When applying pressure though one of the ports, one side of the spool is pushed to one direction hence flow is coming from the work ports.

The PVH is available in two types of connector thread types:

- ¼ BSP
- ½" –20 UNF

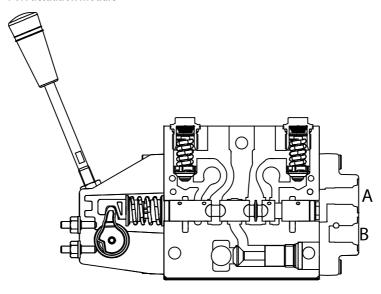

When using the PVH a spool designed for hydraulic actuation must be chosen. These spools have a stiffer spring designed for the higher actuation pressure used in systems with hydraulic controls.

The PVH is to be combined with a PVM.

PVM and PVH - mechanical actuation modules

PVM/PVH oil flow characteristics

The letters AA, A, B, C and D denotes the spool flow sizes ranging from 5 l/min to 65 l/min [from 1.32 to 17.17 US gal/min]. All tests are done by using Tellus 32 @ $21 \text{mm}^2/\text{s}$.

PVG 16 Proportional Valve Group

PVM and PVH - mechanical actuation modules

Oil flow as a function of spool travel

PVAS

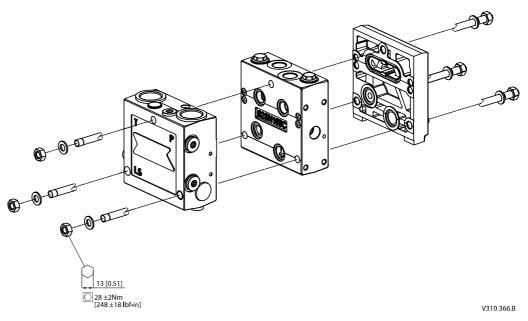

PVAS design

The PVAS consists of three tie rods, six washers and six nuts. The tie rods are inserted through the entire length of the PVG valve stack. The nuts are tightened at the pump side and the end plate.

For certain combinations with PVG 100/16, PVG 120/16 and some PVS 32 the tie rod are thread-mounted into the interface.

Technical characteristics for PVAS

PVE - electrical actuation modules

PVE features

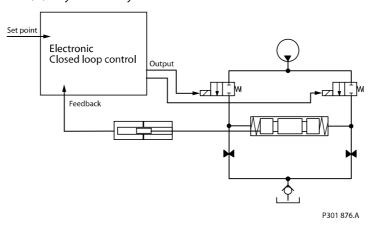

- Electrical actuation
- Spool position output
- Fault monitoring
- Power save

PVE actuation module

The PVE is a means of controlling the flow of the work ports at a distance from the physical valve. The flow is controlled by sending a control signal to the PVE. Result is the spool position being proportional to the electric signal.

PVEO/A/-F hydraulic subsystem

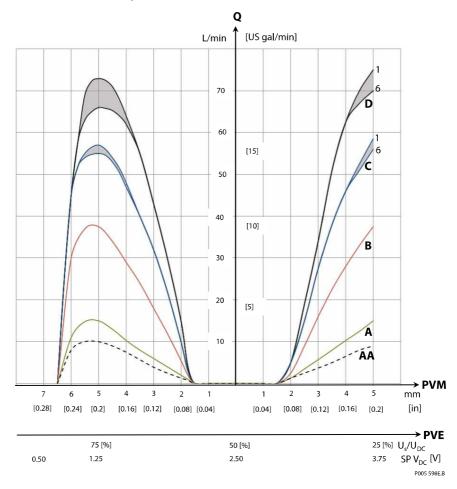

Electrical actuation

The PVEA is powered by the DC voltage source available on the application with any voltage between 11 and 32 V_{DC} inclusive. The control signal for the PVEA is a ratio-metric signal with reference to the supply voltage.

PVE - electrical actuation modules

Oil flow as a function of spool travel

Giving the PVEA a control signal of 50% of supply voltage will make it place the spool in its neutral position, hence no flow to the work ports. A signal (U_s , U_{DC}) between 25-50% or between 50-75% will make the spool move in either direction. At 25 and 75% the spool will be at full stroke at either side.

The PVEA and PVEA-F features an integrated feedback transducer that measures spool movement in relation to the input signal. This feedback is part of the closed loop control of the spool position making the PVEA and PVEA-F capable of compensating for changes in the flow forces on the spool, pilot pressure or the viscosity of the oil.

The PVEO is powered by a fixed voltage of either 12 or 24 V_{DC} . Applying this voltage to one of two pins will make the PVEO actuate the spool to full stroke. When removing the voltage again the spool will return to neutral position.

Spool position output

The PVEA has a build in spool monitoring circuit. This circuit is communicating to the surroundings by an analogue 0-5 V_{DC} pin. The translation between a voltage out on the pin to spool movement can be found in the technical characteristics section of this chapter.

The voltage outputted between 1.25 to 2.5 V_{DC} and 2.5 to 3.75 V_{DC} is directly proportional to the position of the spool and therefore the flow.

The PVEO has no spool position output pin.

PVG 16 Proportional Valve Group

PVE - electrical actuation modules

Fault monitoring

When the voltage on the SP-pin goes to 5 V_{DC} the PVEA has detected an error. The error detection is monitoring the sanity of the command signal, comparing the spool position with the command signal and the closed loop control.

Besides outputting 5 V_{DC} on the spool position pin the PVEA will change the color of the LED for visual recognition of the error. Normally the LED would light green, but in case of a command signal error the LED will be flashing red. If any of the other two errors occur the LED will change its color to constant red.

The PVEO has no fault monitoring.

Power save

The PVEA has a power save mode. This mode is entered when the command signal to the PVEA is below 15% of the supply voltage. Entering power save mode will turn off the power to the solenoid valves. Power save mode can be identified by the LED blinking green at 1 Hz.

The PVEO has no power save mode.

- 2. NC (not connected)
- 3. Vf (float)
- 4. Sp (spool position)
- **5.** Vneg (÷)
- **6.** Vbat (+)

A Warning

When PVEA-F is given float command it will actuate the spool into float state no matter what position in spool has or set point given to PVEA-F.

PVEO pin connector layout

The PVEO is available for simple ON/OFF actuation of the main spool. It has a 4 pin DEUTSCH connector.

<u>Legend:</u>

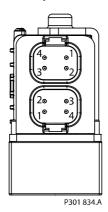

- 1. Supply Vbat when flow is wanted in A direction
- **2.** Vneg (÷)
- **3.** Vneg (÷)
- 4. Supply Vbat when flow is wanted in B-direction

PVE technical data

Technical characteristics for PVEO

Supply voltage U _{DC}	Rated	12 V _{DC}	24 V _{DC}		
	Range	11 to 15 V _{DC}	22 to 30 V _{DC}		
	Ripple	max. 5 %			
Current consumption	320 mA @ 12 V _{DC} 160 mA @ 24 V _{DC}				
Power consumption		4 W			
Oil consumption	Neutral	0.04 l/min			
	Full flow steady state	0.06 l/min			
	Peak	1 l/min			

Technical characteristics for PVEA / PVEA-F

Supply voltage U _{DC}	Rated	11 to 32 V _{DC}	
	Range	11 to 32 V _{DC}	
	Ripple	max. 5 %	
Current consumption at rated voltage		320 mA @ 12 V _{DC} 170 mA @ 24 V _{DC}	
Power consumption		0.5 W	
Oil consumption	Neutral	0.04 l/min	
	Full flow steady state	1 l/min	
	Peak	1.3 l/min	
Signal voltage	Neutral	0.5 • U _{DC}	
	A-port	0.25 • U _{DC}	
	B-port	0.75 • U _{DC}	
Signal current at rated voltage	•	0.25 to 70 mA	
Input impedance in relation to neutral		12 kΩ	
Input capacitor	100 μF		
SP pin current	2 mA		
SP pin resolution		250 steps from 0-5 V _{DC}	

PVE – electrical actuation modules

Technical characteristics for PVE-CI

Supply voltage U _{DC}	Rated	11 to 32 V _{DC}		
	Range	11 to 32 V _{DC}		
	Ripple	max. 5 %		
Current consumption at rated voltage		320 mA @ 12 V _{DC} 170 mA @ 24 V _{DC}		
Power consumption		0.5 W		
Oil consumption	Neutral	0.04 l/min		
	Full flow steady state	1 l/min		
	Peak	1.3 l/min		

Refer to PVE-CI, Series 6, Technical Information L1505234 for further information.

SP pin

Voltage	Translation
0.5 V _{DC}	Float (B-direction)
1.25 V _{DC}	Full flow B-port
2.5 V _{DC}	Neutral
3.75 V _{DC}	Full flow A-port
5.0 V _{DC}	Error

PVEO/PVEO-CI reaction time

Reaction time	A-direction	B-direction
Neutral to full spool stroke	173 ms	105 ms
Full spool stroke to neutral	396 ms	565 ms

PVEA/PVEA-F/PVEA-CI reaction time

Reaction time	A-direction	B-direction
Neutral to full spool stroke	188 ms	142 ms
Full spool stroke to neutral	125 ms	120 ms

PVEO and PVEA/PVEA-F oil consumption

PVE type	PVEO	PVEA/PVEA-F
Neutral position	0.04 /min [0.01 US gal/min]	0.04 l/min [0.01 US gal/min]
Actuating to full stroke	0.6 l/min [0.16 US gal/min]	1 l/min [0.26 US gal/min]
Full stroke steady state	1 l/min [0.26 US gal/min]	1.3 l/min [0.34 US gal/min]

Technical Information

PVG 16 Proportional Valve Group

PVE – electrical actuation modules

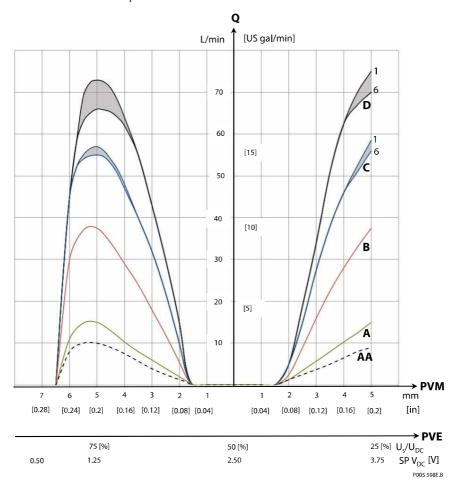

Fault monitoring overview

PVE Type	Fault monitoring	Delay before error out	Error mode	LED light
PVEO	No fault monitoring	_	_	_
PVEA	Passive	250 ms	No fault	Green
			Input signal faults	Flashing red
			Transducer (LVDT)	Constant red
			Close loop fault	

PVE oil flow characteristics

The letters AA, A, B, C and D denotes the spool flow sizes ranging from 5 l/min to 65 l/min [from 1.32 to 17.17 US gal/min]. All tests are done by using Tellus 32 @ 21mm²/s.

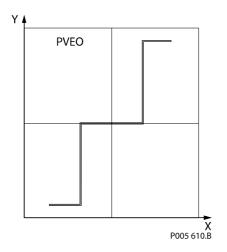

Oil flow as a function of spool travel

PVEA/PVEA-F and PVEA-CI voltage-position diagram

PVHC, high current actuation module – electrical

- Electrical actuation
- Pin layout

PVHC high current actuator

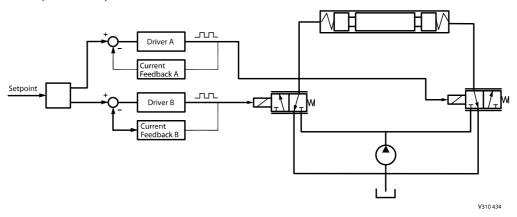

The PVHC is a means of controlling the flow of the work ports at a distance from the physical valve. The flow is controlled by sending a PWM signal to the one of two pressure reduction valves. Result is the spool position being proportional to the current.

Technical Information PV

PVG 16 Proportional Valve Group

PVE - electrical actuation modules

PVHC hydraulic subsystem

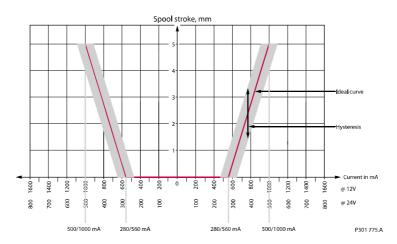

The PVHC needs 25 bar pilot pressure and is therefore used together with PVBS and PVP for hydraulic (PVH) actuation.

Electrical actuation

The PVHC is powered and controlled by a PWM DC voltage source available on the application with either $12 \text{ or } 24 \text{ V}_{DC}$ dependent on the type of PVHC.

PVHC characteristic

Giving the PVHC a PWM signal with a current of 0 mA will make it place the spool in its neutral position, hence no flow to the work ports. Increasing the current on one of the two pressure reduction valves will make the spool move in one direction.

The PVHC does not feature any integrated feedback transducer to measure the spool position. Therefore it does not feature any closed loop control of the spool.

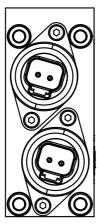

Versions and code numbers

PVHC versions and code numbers

Description	Code number	
	12 V _{DC}	24 V _{DC}
PVHC, electrical actuation, proportional control	11126941	11127535

PVE – electrical actuation modules

PVHC pin layout – DEUTSCH version

V310 435

Technical characteristics for PVHC

PVHC technical characteristics

Supply voltage U _{DC}	12 V _{DC}	24 V _{DC}		
Controller output current	0 – 1200 mA	0 – 600 mA		
Resistance	1 Ω	0.25 Ω		
Pilot pressure control range	5 – 15 bar [72.5 – 217.5 psi]			
Recommended dither frequency	40 Hz			
Recommended amplitude	250 mA			

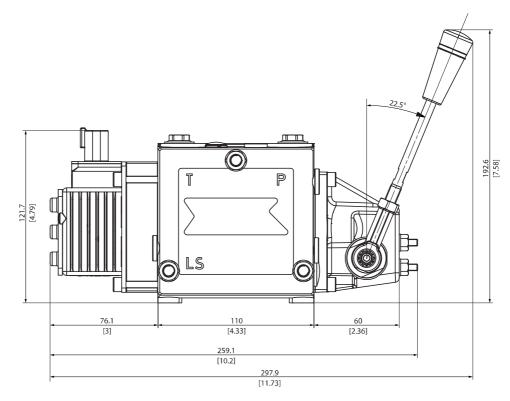

PVHC reaction time

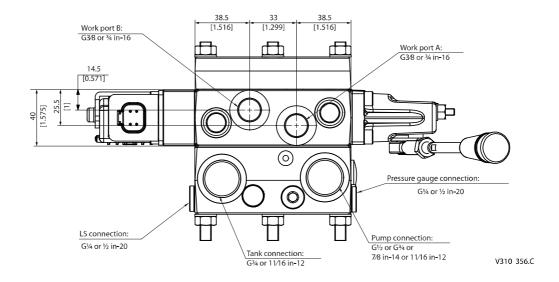

From neutral position to max. spool travel at power on	A-direction	<90 ms
	B-direction	<90 ms
From max. spool travel to neutral position at power off	A-direction	<90 ms
	B-direction	<90 ms

Hydraulic system

Hydraulic system efficiency

A complete hydraulic system can be implemented in many different ways. There is no sole answer to: which system solution is the right one? The solution will depend on what is the aim of the vehicle manufacturers, if they are aiming for high productivity, and/or a low fuel consumption, and/or a compact design, and/or a high operator comfort, etc.

An important topic to consider when it comes to system design is *energy efficiency*. Components in a system have their individual efficiency and as such the components contribute to the total energy consumption. This energy consumption is directly proportional with the emission of the application and the operating costs.

The power needed to generate the flow and pressure for each system function is vital as surplus energy used to generate excess flow and pressure is converted into heat and thereby loss.

There are generally three types of mobile hydraulic systems:

- Fixed displacement with constant flow,
- Variable displacement with constant pressure and
- Variable displacement with load sense (LS).

Fixed displacement system with constant flow

Uses a pump with fixed displacement to generate a fixed flow to the system. In standby the flow is send from the pump through the valve and back into the reservoir. Whenever a consumer requests a portion of the flow to perform a work function, the fixed displacement system brings the entire flow up to the load pressure. The valve will then divide the flow into work port flow and surplus flow sending this back to the reservoir.

The efficiency of a fixed displacement system is directly proportional to the percentage of the total flow used by the consumer. If the consumer uses 10% of the total flow available the fixed displacement system is 10% efficient. If the consumer uses 75% of the total available flow the system is 75% efficient.

Variable displacement system with constant pressure

Uses a variable displacement pump to regulate the flow to system consumer needs. The flow is always pressurized to the setting of the pump pressure compensator independent of the consumer(s) pressure need. In standby the pressure remains at full system pressure and only leakage flow is circulated back to the reservoir. Whenever a consumer request a flow to perform a work function the pump will deliver this flow only, but at full system pressure, independent of the function pressure need.

The efficiency of a fixed displacement system is directly proportional to the percentage of the total pressure needed to perform the work, If 10% of the pressure is needed the fixed displacement system is 10% efficient. If 75% of the pressure is needed the fixed displacement system is 75% efficient.

Variable displacement system with load sense

Uses a variable displacement pump to give the consumer the requested flow at the needed pressure. In standby only pump leakage is circulated back to reservoir – at only margin pressure. Whenever a consumer requests a flow the pump delivers this flow at needed pressure plus a margin pressure to compensate internal resistance and system control.

The efficiency of a LS system, despite its pressure control, is not proportional to the flow or pressure but a result of the pump margin pressure setting.

The easiest way to compare the efficiencies of the systems is to make an example. Considering a pump with a maximum flow rate of 200 l/min [52.8 US gal/min] and a system pressure of 300 bar [4351 psi].

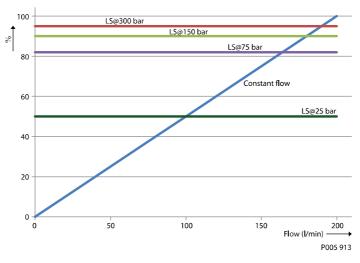

A comparison of fixed and variable displacement systems gives the LS system a huge efficiency advantage over the fixed displacement system, especially in the high pressure and low-to-medium flow applications.

Technical Information

PVG 16 Proportional Valve Group

Hydraulic system

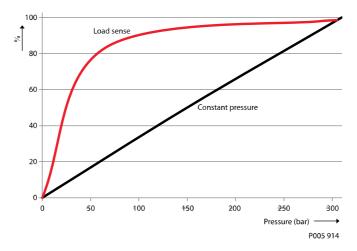

Fixed vs variable displacement system

Considering multiple consumers where the high flow work functions are seldom used, the LS system will increase the advantage over the fixed displacement system.

A comparison of fixed and variable displacement systems gives the variable displacement system an efficiency advantage over the fixed displacement system in the lower pressure range of an application.

Fixed vs variable displacement system

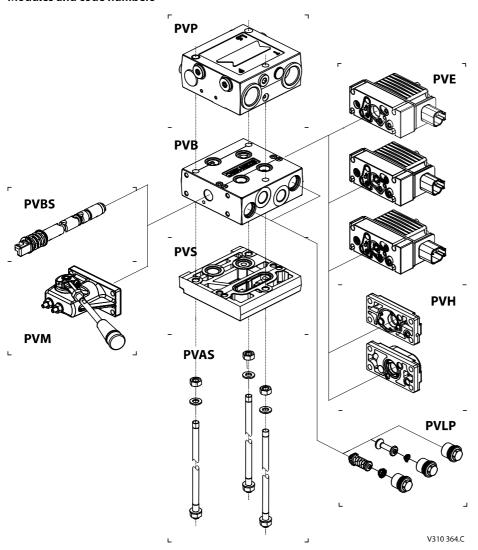

Considering multiple consumers at different pressures the variable displacement system will increase the efficiency over the fixed displacement system.

Although the variable displacement system is the most complex of the three systems it potentially offers great advantages in terms of efficient use of energy and in turn the compliance with power management requirements. The PVG family offers products for both constant flow and load sense systems for the best solution for the mobile hydraulic system.

Products we offer:

- **Bent Axis Motors**
- Closed Circuit Axial Piston **Pumps and Motors**
- Displays
- Electrohydraulic Power Steering
- Electrohydraulics
- Hydraulic Power Steering
- **Integrated Systems**
- Joysticks and Control **Handles**
- Microcontrollers and Software
- Open Circuit Axial Piston **Pumps**
- Orbital Motors
- PLUS+1° GUIDE
- **Proportional Valves**
- Sensors
- Steering
- **Transit Mixer Drives**

Danfoss Power Solutions is a global manufacturer and supplier of high-quality hydraulic and electronic components. We specialize in providing state-of-the-art technology and solutions that excel in the harsh operating conditions of the mobile off-highway market. Building on our extensive applications expertise, we work closely with our customers to ensure exceptional performance for a broad range of off-highway vehicles.

We help OEMs around the world speed up system development, reduce costs and bring vehicles to market faster.

Danfoss - Your Strongest Partner in Mobile Hydraulics.

Go to www.powersolutions.danfoss.com for further product information.

Wherever off-highway vehicles are at work, so is Danfoss. We offer expert worldwide support for our customers, ensuring the best possible solutions for outstanding performance. And with an extensive network of Global Service Partners, we also provide comprehensive global service for all of our components.

Please contact the Danfoss Power Solution representative nearest you.
